- always keep your eyes up

ball handling

have one foot forward, what can you do with drop step, not sure about that

Brunson's hand

and, his heel is off the ground before shot

 perplexity

what shoot the shooting hand look like after finishing a shot, I noticed the middle finger and thumb is down for Jalen Brunson

After Jalen Brunson finishes his shot, his shooting hand often shows a distinct follow-through: his wrist is relaxed and snapped forward, and you may notice that his middle finger and thumb are both pointing downward. This is a result of his smooth, soft release and strong wrist snap, which helps generate arc and control on the shot^{1 1^1 5}. The downward position of the middle finger and thumb after release is typical for shooters who emphasize a relaxed, natural follow-through, and for Brunson, it reflects his focus on a soft touch and accuracy^{1 1^1 5}. This hand position is not unique to Brunson but is especially noticeable in his shooting mechanics.

*
**

explain soft release of the ball

quick snap of the ball on the wrist?

A *soft release* in basketball refers to letting the ball leave your hand smoothly and gently, with a controlled, relaxed motion rather than a forceful or rigid push. The key component of a soft release is the quick snap of the wrist at the end of your shooting motion. This wrist snap imparts backspin on the ball, which stabilizes its flight, helps it "soften" as it hits the rim, and increases the chances of a favorable bounce if the shot is slightly off 2 2 4.

A proper soft release involves:

- The shooting arm fully extended.
- The wrist snapping forward in a fluid, relaxed motion.
- The fingers (especially the middle and index) following through toward the basket.
- The ball leaving the fingertips softly, with noticeable backspin 2 2 4.

The quick wrist snap is crucial—it's what generates the backspin and gives the shot its soft touch, making the ball more likely to bounce in rather than out if it hits the rim 2 3 5. A rigid or overly forceful release can lead to flat, hard shots that are less forgiving on the rim 2 4.

*
**

so go up softly then snap

Exactly! Here's a simple breakdown:

1. **Go Up Softly:** As you rise into your shot (whether off the dribble or catch), keep your motion smooth and controlled. Your shooting arm and body should move upward in a relaxed, fluid way—don't rush or tense up.
2. **Snap the Wrist:** At the top of your shot, when you're fully extended, finish with a quick, relaxed snap of your wrist. This is where the "soft release" happens. Your fingers should point toward the basket, and the ball should roll off your fingertips with good backspin.

Key Tips

- **Don't force the ball:** Let the upward motion and wrist snap do the work.
- **Stay relaxed:** Tension in your arm or hand can make your shot flat or hard.
- **Watch great shooters:** Players like Jalen Brunson, Steph Curry, and Ray Allen all have a soft, snappy finish.

In short: Go up softly, then snap your wrist for a smooth, controlled, and accurate shot!

what is the basketball term finish with a 9 or 7

There is no widely recognized basketball term that specifically means "finish with a 9 or 7." If you are referring to a type of scoring play, player statistic, or rule, none of the standard basketball glossaries or rules mention a term linked to the numbers 9 or 7 as a way to describe a finish, play, or outcome

1_2

1_5

1_4

.

If you meant something else, such as a rule number (like Rule 9 or 7) or a specific play that ends with those digits on the scoreboard, please clarify, as there is no direct basketball terminology that fits "finish with a 9 or 7."

to get a highly valued shot

To "get a highly valued shot" in basketball means creating or taking shots that statistically offer the best return in points per attempt. The most highly valued shots are:

- **Layups and dunks (at the rim):** These are the most efficient, averaging about 1.22 points per possession, because they are high-percentage shots taken close to the basket
2_3
2_5
.
- **Open catch-and-shoot three-pointers:** These are the next most valued, averaging around 1.05 points per possession, since three points are awarded for a make and good shooters can hit them at a high rate
2_3
2_5
.
- **Free throws:** On a per-possession basis, free throws are actually the most efficient shot, averaging about 1.55 points per possession for the league average shooter
2_3
.

Teams and players prioritize getting these types of shots-layups/dunks, open threes, and free throws-because they maximize scoring efficiency and overall offensive output

2_3

Zoom Action

Zoom action is a popular basketball offensive set that combines an off-ball down screen with a dribble handoff. Here's how it works:

- A player on the perimeter sets a down screen for a teammate.
- The teammate uses the screen to get open and then immediately receives a dribble handoff from the player with the ball.

- This sequence creates space, confuses defenders, and opens up driving lanes or shooting opportunities, especially for guards and wings

3_2

3_4

3_5

.

- Teams often use Zoom action to generate high-percentage shots and to keep defenses guessing with multiple options after the initial handoff

3_1

3_2

3_5

.

High Ball Screen

A **high ball screen** (also called a "spread" or "top" ball screen) is a pick set near the top of the key, usually by a big man for the primary ball handler:

- The screener positions themselves high on the court, often above the three-point line.
- The ball handler uses the screen to attack downhill, looking to drive, shoot, or pass depending on how the defense reacts.
- The screener can "roll" to the basket, "pop" out for a shot, or create mismatches if defenders switch

3_3

3_6

.

- This is one of the most common actions in modern basketball, especially in the NBA, because it creates space and forces defenses to make tough decisions

3_3

3_6

.

In summary:

- *Zoom action* = down screen + dribble handoff, often on the perimeter, to create movement and open shots.

- *High ball screen* = screen set high on the court for the ball handler, enabling drives, shots, or passes depending on defensive coverage.

1. shoulder bump
2. driving right then left shoulder bump

like how little Jose would go against Speedy without passing

one two pull

the other is shot then step thru

increase range

land with wider base, Steph does this all the time

<https://www.youtube.com/shorts/h2dM7v4vufY>

game summary

In basketball, there's too many people.

Too competitive, You put your hands around Miguel, you pull him down.

Or guard against Speedy, what had happened was I would just like, you know, grab the ball and then just grab his hand and push his hand, it was a foul or something like that when he was coming fast.

But then when I was rushing up the court, you know, like I'll dribble, but then he'll put a hand on me and that's a foul, you know, impeding my path.

So just like, when you just slow down or something like that, just put a shoulder, you know.

See what you can do about that. Get around someone slowly. Not quick, because they can go and reach, you know. Don't let them reach.

And shoot, when someone's running at you, so you just have to count, you know. Breathe, and then you got your, right, you got your head, you got your elbow, you got your release. Something like that, you know. Belly, head, release.

ankle injuries

look up basketball players hurting their ankles when they land after shooting

Basketball players frequently hurt their ankles when landing after shooting or rebounding due to the sport's high demands for jumping, quick direction changes, and the risk of landing on another player's foot

1_5

1_2

1_6

. The most common ankle injuries include sprains, strains, and sometimes fractures, often occurring when a player lands awkwardly or on someone else's foot

1_2

1_5

1_3

.

A recent example is Duke's Cooper Flagg, who suffered a sprained ankle after landing awkwardly following a rebound; X-rays were negative for fracture, but he missed the remainder of the game and his return was uncertain

1_7

.

Prevention is challenging because many incidents are accidental, but strategies include:

- Wearing proper footwear with ankle support
1_2
- Strengthening ankle muscles and improving balance
1_3
1_5
- Practicing safe landing mechanics and using ankle braces or taping for additional support
1_2
1_4

Fatigue increases risk, as tired players are more likely to have poor landing mechanics
1_5

. Even with preventive measures, some risk remains due to the unpredictable nature of play and collisions
1_6

.

how about videos

There are many videos showing basketball players injuring their ankles when landing after shooting or rebounding. Some notable recent examples include:

- **Jayson Tatum's ankle injury:** Multiple video clips capture Tatum landing on Domantas Sabonis' foot after a three-point shot, immediately clutching his ankle in pain. The play was ruled a flagrant foul because Sabonis stepped into Tatum's landing space, causing the injury. Tatum had to leave the game for treatment after shooting his free throws

2_1

2_7

2_8

-
- **Cooper Flagg's injury:** Video from the ACC Tournament shows Duke's Cooper Flagg rolling his left ankle after grabbing a rebound and landing on another player's foot. He was helped off the court and did not return to the game

2_2

-
- **Chris Paul's twisted ankle:** In the 2021 NBA Finals, Chris Paul twisted his ankle after landing on Brook Lopez's foot during a three-point attempt. The play was reviewed and ruled a flagrant foul for invading the shooter's landing space

2_4

-
- **Jalen Brunson's ankle turn:** A recent Instagram video shows Brunson turning his ankle badly after landing on Austin Reaves' foot, visibly limping to the bench

2_5

You can find these clips on platforms like YouTube, ESPN, Instagram, and TikTok by searching for the players' names and "ankle injury" or "landing injury"

a lot of these is jumping high then landing with an ankle turned inwards

Yes, most basketball ankle injuries from landing after a jump involve the ankle turning inward-this is called an "inversion" injury. It typically happens when a player lands on another player's foot or lands awkwardly, causing the foot to roll inward and stretching or tearing the ligaments on the outside of the ankle

3_1

3_3

3_4

3_5

. This inward rolling is the most common cause of ankle sprains in basketball, especially during high jumps and landings

3_1

3_4

3_5

.

Biomechanical studies confirm that forefoot landings, which often happen in basketball, put the ankle in a position (plantar flexed with inward rotation) that increases the risk of these inward-turning sprains

3_2

.

how to prevent this during a basketball shot

To help prevent ankle injuries when landing after a basketball shot, focus on these proven strategies:

- **Strengthen ankle and lower leg muscles:** Regular exercises like calf raises, resistance band workouts, and balance drills (such as single-leg stands) improve joint stability and help your ankles better absorb landing forces

4_2

4_3

4_5

4_6

4_7

.

- **Practice balance and proprioception:** Training your body's ability to sense and control joint position-using balance boards or single-leg exercises-can significantly reduce the risk of rolling your ankle on landings

4_2

4_3

4_7

4_9

.

- **Use proper landing mechanics:** Work with coaches or trainers to learn and practice safe landing techniques, such as landing on both feet, keeping knees and hips slightly bent, and avoiding landing on the side of your foot

4_2

4_5

4_9

.

- **Wear supportive footwear:** Choose basketball shoes that fit well, have high tops, and provide good ankle support. Replace shoes when the tread wears out

4_3

4_4

4_5

.

- **Consider ankle braces or taping:** Both methods offer extra support and have been shown to reduce ankle sprain risk, especially if you have a history of ankle injuries

4_1

4_2

4_6

.

- **Warm up and stretch:** Always start with a dynamic warm-up and stretching routine before playing to prepare your muscles and joints for jumping and landing

4_4

4_5

4_8

.

- **Play on safe surfaces:** Ensure the court is clean, dry, and free of hazards to minimize accidental slips or awkward landings

4_4

.

By combining these approaches-especially strengthening, balance training, and external support-you can lower your risk of ankle injuries during basketball shots and landings

4_2

4_3

4_5

4_6

.

[4_9] <https://pmc.ncbi.nlm.nih.gov/articles/PMC3752192/>

is there a way to when you feel about to inversion injury to do something about it

When you feel an inversion (inward rolling) ankle injury about to happen during basketball, your body's ability to react quickly—called proprioception—can sometimes help you minimize the damage. With strong proprioceptive skills and ankle strength, you may be able to reflexively shift your weight, hop, or take pressure off the rolling ankle, potentially reducing the severity of the sprain

5_7

5_8

.

However, these reactions are mostly automatic and depend on your training. Regular balance and proprioception exercises, like single-leg stands, balance board drills, and ankle strengthening routines, can improve your body's reflexes and reaction time

5_2

5_5

5_8

. Some experienced players report that with good body awareness, they can sometimes "save" themselves mid-movement by quickly taking weight off the turning ankle or letting themselves fall safely instead of trying to stay upright

5_7

.

Still, once the ankle starts to roll, there's often little you can consciously do in the split second before injury. The best defense is preparation: train your balance and ankle strength, wear supportive shoes, and consider braces or taping if you're prone to sprains

5_5

5_7

5_10

. This way, your body is more likely to react quickly and protect itself when you sense a sprain coming.

I see when the weight completely comes into that ankle

When you see the weight completely coming onto the ankle during an inward (inversion) roll, that's the critical moment when most ankle sprains occur. At this point, the lateral ligaments-especially the anterior talofibular ligament-are suddenly overloaded and can tear, leading to pain, swelling, and instability

6_1

6_2

. The ankle joint is designed to bear very high loads, but when the foot lands in a turned-in (supinated and plantar-flexed) position, the force is concentrated on the outside of the ankle, making it highly vulnerable to injury

6_3

6_4

.

Biomechanical studies show that landing with the ankle in more plantar flexion and supination (toes pointed down and foot turned in) increases the risk of a sprain, especially if all your body weight comes down at once in that position

6_4

6_5

. If you have chronic ankle instability, the risk is even higher, as the joint may invert further and faster than a healthy ankle can resist

6_5

.

Once the full body weight is committed to the inverted ankle, the chance to prevent injury is extremely limited. That's why prevention focuses on strengthening, balance training, and proper landing mechanics-so your body is less likely to get into that vulnerable position in the first place

6_4

6_5

6_6

.

so try to land in the inner part with knees turned in rather than on the edge of the foot

No, you should not try to land on the inner part of your foot or with your knees turned in. This actually increases your risk of both ankle and knee injuries.

Proper landing technique in basketball involves:

- Landing with your knees and feet pointing in the same direction, aligned over your toes-not caving in or turning inwards

7_1

7_5

7_6

.

- Absorbing the impact by bending your hips, knees, and ankles, keeping your weight centered and landing softly on the balls/midfoot, then rolling to the heel

7_3

7_5

7_6

.

- Avoiding letting your knees collapse inward (valgus), as this can strain your knees and ankles and increase risk of serious injuries like ACL tears and ankle sprains

7_1

7_5

7_10

.

Key points:

- Land with your knees tracking over your toes.
- Keep your hips, knees, and ankles flexed and aligned.
- Do not intentionally turn your knees or feet inward or try to land on the inner edge of your foot

7_1

7_5

7_6

.

This alignment helps your muscles absorb landing forces and protects your joints from injury. Practicing these mechanics will reduce your risk of both ankle inversion sprains and knee injuries.

I see so like when jumping off high you want to land with knees bent

Yes, when jumping from a height-like after a basketball shot-it's crucial to land with your knees bent. Bending your knees, along with your hips and ankles, helps absorb the impact and reduces the stress on your joints. Proper landing technique includes:

- Bending your knees, hips, and ankles as you land to cushion the force
 - 8_2
 - 8_5
 - 8_6
 - 8_8
-
- Keeping your knees aligned over your toes-not letting them collapse inward-to protect both your knees and ankles
 - 8_5
 - 8_7
-
- Landing softly on the balls of your feet, then rolling to your heels, rather than landing stiff-legged or flat-footed
 - 8_2
 - 8_5
-

This technique distributes the landing forces through your muscles instead of your joints, lowering the risk of injury and improving your overall athletic performance

8_5

training for stamina

Sprinting can be an excellent tool for building stamina when incorporated strategically into your training. Here's how you can use sprint work to improve your endurance:

1. **Interval Training:** Alternate between sprint efforts and recovery periods. For example:
 - 30-second all-out sprints followed by 1-2 minutes of walking/jogging
 - 8-12 repetitions per session
 - 2-3 sessions per week
2. **Fartlek Training:** Mix sprints into longer, slower runs at random intervals (e.g., sprint to the next telephone pole, jog to the next tree, etc.)
3. **Hill Sprints:** Sprint up a hill for 20-30 seconds, walk back down for recovery. The incline adds resistance that builds both power and endurance.
4. **Ladder Workouts:** Gradually increase and then decrease sprint distances (e.g., 100m, 200m, 400m, 200m, 100m) with appropriate rest periods.
5. **HIIT (High-Intensity Interval Training):** Combine sprints with other exercises like burpees, mountain climbers, or squats for full-body conditioning that improves cardiovascular endurance.

Unlike steady-state cardio, sprint training improves your anaerobic threshold and teaches your body to clear lactic acid more efficiently. This translates to better performance during sustained efforts.

The key is progressive overload - gradually increasing the number of sprints, reducing rest time, or extending sprint distances as your fitness improves.

Remember to warm up thoroughly before sprint work and incorporate adequate recovery days to prevent injury and allow adaptations to occur.

You're absolutely right about that concern. Hill sprints on cement can be tough on the knees due to the increased impact forces and the angle of incline. Here are some alternatives that can give you similar stamina benefits without the knee strain:

1. **Grass or trail hill sprints:** Find hills on softer surfaces like grass, dirt trails, or athletic fields which absorb impact better than cement.
2. **Sand hill sprints:** If available, sand provides an excellent low-impact surface that adds resistance while protecting joints.

3. **Stair climbing:** Stadium stairs or outdoor steps typically have more consistent grades and often rubber or wood surfaces that are easier on joints.
4. **Incline treadmill sprints:** Most treadmills have cushioning systems designed to reduce impact forces.
5. **Bike hill intervals:** Cycling uphill (either outdoors or on a stationary bike) provides the resistance and cardiovascular benefits without the impact.
6. **Sled pushes/pulls:** These mimic the resistance of hill sprints without the impact of running.
7. **Swimming sprints:** For truly zero-impact sprint training that builds tremendous stamina.
8. **Elliptical or rowing sprints:** Both offer ways to do high-intensity intervals with minimal joint stress.

If you're set on doing hill work on foot but concerned about your knees, proper footwear with good cushioning and making sure you're not overtraining are also important factors to consider. Sometimes alternating between different types of these workouts can help avoid overuse injuries while still building stamina.

protective dribble

When you're running down the court by yourself with two or more defenders closing in, it's natural to want to look back to assess their position. However, looking back can increase your risk of losing control of the ball. Here's how you can safely check behind you without losing possession:

Techniques to Maintain Ball Control While Looking Back

1. Master Dribbling Without Looking Down

- The foundation is being able to dribble confidently without watching the ball. This comes from lots of repetition and muscle memory. The more comfortable you are with your dribble, the easier it is to keep your head up and glance behind you without losing control.
- Practice dribbling drills that force you to keep your eyes up, such as dribbling around cones or catching tennis balls while dribbling, to simulate reacting to defenders and improve your court vision.

2. Use Protective Dribbling Moves

- Employ moves like the *behind-the-back dribble* or *crossover* to shield the ball from defenders as you glance over your shoulder. The behind-the-back dribble, in particular, allows you to keep your body between the ball and the defenders, making it harder for them to steal it while you check your surroundings²⁵.
- When executing a behind-the-back dribble, snap the ball quickly and with enough power so you don't have to look down for long. Even elite players may glance down briefly, but the key is to get your eyes back up as quickly as possible⁵.

3. Keep the Ball to Your Side or Back

- Instead of dribbling directly in front, control the ball at your side or slightly behind you. This positioning helps protect the ball and gives you the freedom to quickly glance back without exposing the ball to defenders¹².

4. Use Peripheral Vision

- Train your peripheral vision to track defenders while focusing forward. With practice, you can sense where defenders are without fully turning your head, reducing the risk of losing the ball.

Practical Drill

- Practice running at speed while dribbling and occasionally glancing over your shoulder, using the behind-the-back or side dribble. Start slowly and increase speed as you gain confidence. Add a partner or coach to simulate defensive pressure, forcing you to make quick, protected glances.

Key Points

- Build confidence through repetition so dribbling becomes second nature³.
- Use protective dribble moves (especially behind-the-back) to shield the ball when checking behind you²⁵.
- Keep the ball to your side, not directly in front, to reduce risk when glancing back¹².
- Limit the time your eyes are off the court—quick glances only, then refocus ahead⁵.

By developing these habits, you'll be able to look back when necessary without fear of losing the ball, even under defensive pressure.

Answer from Perplexity: pplx.ai/share

control vs. going fast like in baseball, a drag car vs. stock cars

Drag Car vs. Stock Car: Speed vs. Endurance

These two types of racing vehicles represent different extremes in motorsport philosophy:

Drag Car

- **Purpose:** Pure straight-line acceleration and top speed over short distances (typically 1/4 mile)
- **Design focus:** Maximum power-to-weight ratio
- **Engine:** Often supercharged or turbocharged with extreme horsepower (1,000+ HP)
- **Durability:** Built for intense bursts of a few seconds
- **Features:** Specialized components like parachutes, wheelie bars, specialized tires that heat up quickly
- **Race duration:** Seconds (typically 3-10 seconds)
- **Components:** May need rebuilding after just a few runs

Stock Car (NASCAR-style)

- **Purpose:** Sustained high-speed racing with handling requirements
- **Design focus:** Balance of power, endurance, and handling
- **Engine:** Powerful but reliable (700-900 HP)
- **Durability:** Built to last 500+ miles of continuous racing
- **Features:** Aerodynamic package for downforce, cooling systems for long runs
- **Race duration:** Hours (typically 2-4 hours)
- **Components:** Built to withstand hundreds of miles of wear

The key difference is in their optimization targets. A drag car sacrifices everything for momentary performance - it's like a sprinter who trains purely for explosive power. A stock car needs to balance power with reliability - more like a marathon runner who needs sustained performance.

This contrast shows up most clearly in how their engines are tuned: drag cars often run extremely rich fuel mixtures that would destroy an engine if maintained for hours, while stock cars need precise fuel management that balances power with efficiency and longevity.

hand is part of the ball

If you lose the ball while dribbling because a defender swipes at your hand, whether it is a foul depends on where and how the contact occurs:

- **"Hand is part of the ball" Rule:** If your hand is in contact with the ball and the defender strikes your hand while making a legitimate play for the ball, that contact is generally *not* considered a foul. The rule is interpreted so that the hand, *while in contact with the ball*, is treated as part of the ball⁴²⁶. This applies to dribbling, shooting, or holding the ball.
- **Limits and Exceptions:** If the defender hits your hand *when it is not in contact with the ball*, or strikes your wrist, arm, or any part below the wrist, it is a foul²⁶. Also, if the contact is excessive, aggressive, or not incidental to a play on the ball, referees may call a foul even if some hand contact occurs⁶.
- **NBA and High School Differences:** The "hand is part of the ball" principle is recognized in the NBA and often in high school rules, but enforcement can vary by league and referee²⁶.

In summary: If a defender swipes at your hand *while your hand is in contact with the ball* and dislodges it, it is typically *not* a foul—this is the scenario where people say "the hand is part of the ball." If the defender hits your hand when it is *not* touching the ball, or hits your wrist or arm, it should be called a foul²⁴⁶.
